

IFE Trisomat

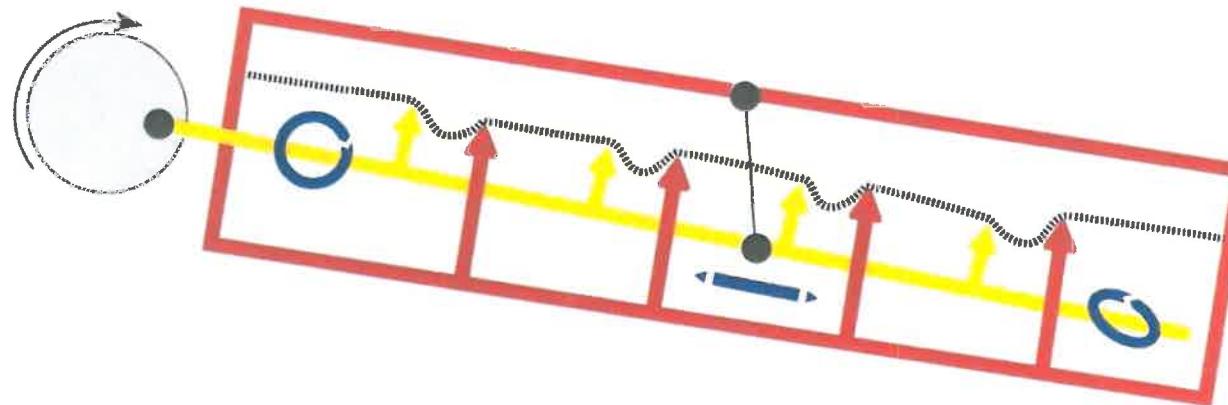

Operating principle:

Two frames moving relative to each other, flexible mounted within a static support structure. Transverse mesh support beams are alternatively attached to the inner and outer frames.

The beams cause the mesh sections to cyclically stretch and relax.

High accelerations result which obviate pegging and blinding.

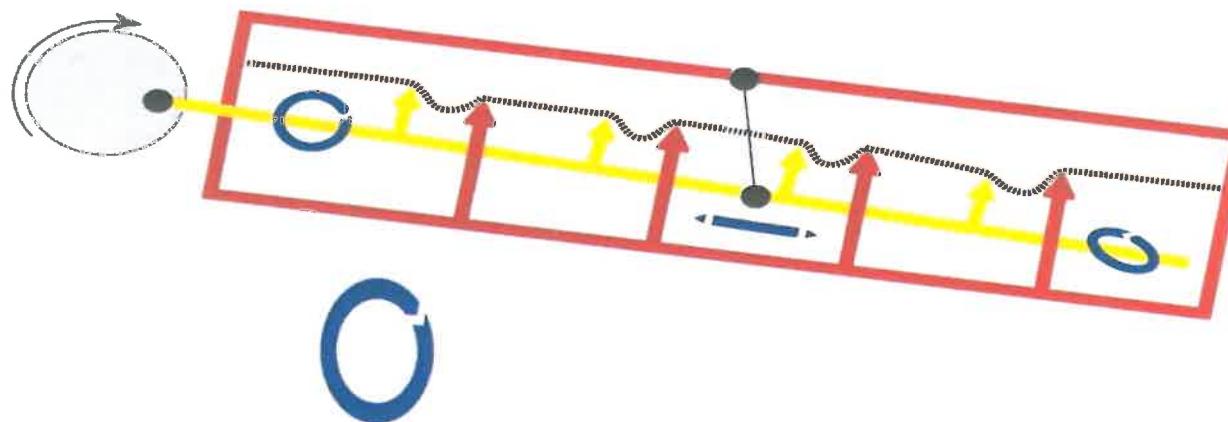

IFE Trisomat

The Trisomat's unique '3-phase motion' ensures:

- Quick stratification of material at the feed end**
- Efficient screening in the central section**
- Increased „near-size“ screening efficiency at the discharge end**

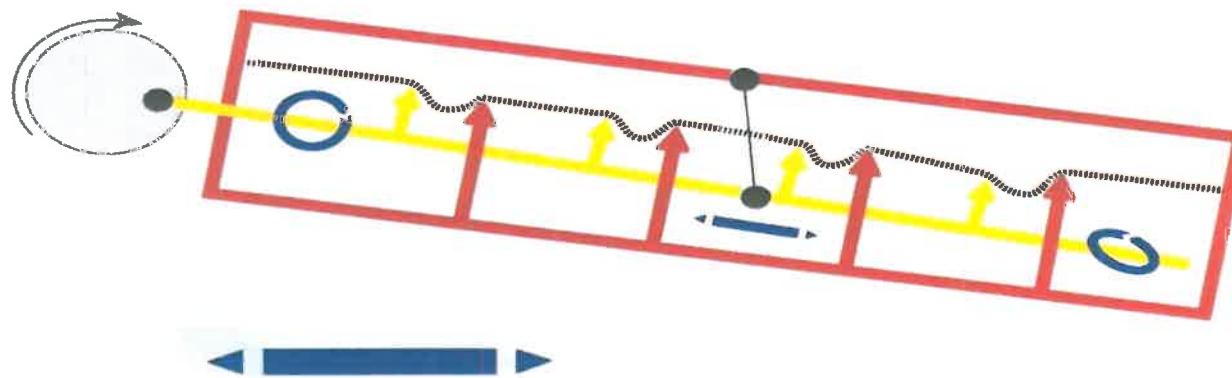

IFE Trisomat

Feed end

The circular motion at the feed end
assists a stratification of even the most
difficult materials and conveying the feed
material forward.

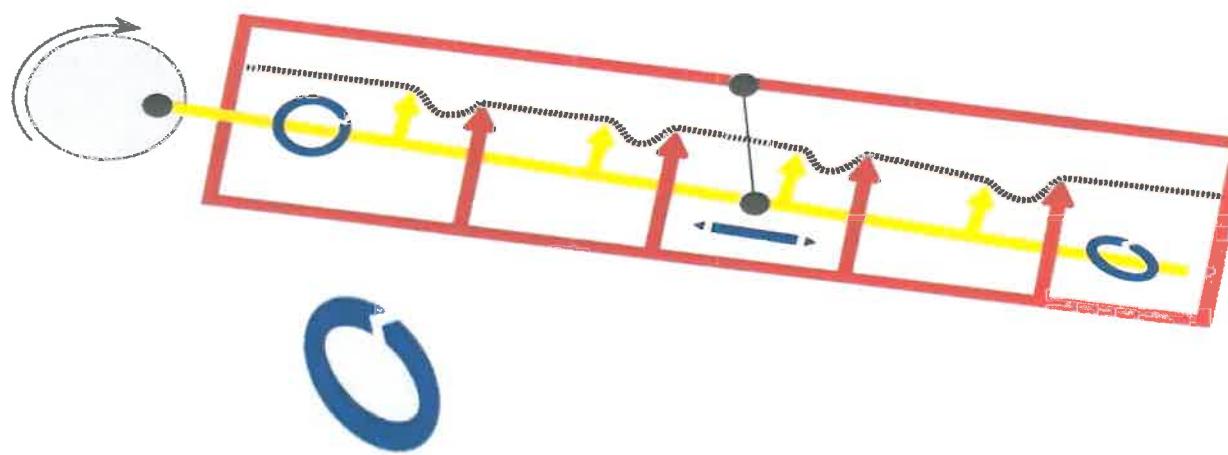

IFE Trisomat

Central section

A linear motion in the central section of the deck area ensures optimum contact between material and mesh thus improving screening efficiency.

IFE Trisomat

Discharge end

The reverse elliptical movement at the discharge end retards the material and maintains a bed depth ensuring efficient „near-size“ particle extraction.
